

How to cdm (Conceptual Data Model) update

How to cdm (Conceptual Data Model) update

This documentation is the procedure every developer needs to follow when they ask for an update of the database's schema or CDM.

The different steps needs to be done in the following order:

- [How to cdm update](#)
- [Developer actions](#)
 - [Update of the Excel file](#)
 - [First merge request by the developer](#)
- [Technical direction actions](#)
 - [Update of the CDM and linked scripts](#)
 - [First merge request by the technical direction](#)
 - [Java and SQL modifications by the technical direction](#)
 - [Second merge request by the technical direction](#)
- [Developer actions](#)
 - [Synchronization with develop and new developments](#)
 - [Second merge request by the developer](#)

Developer actions

Update of the Excel file

 **Applicable only if an update of data model has been identified**

Prerequisites

A Product Responsible must have validated the CDM modification request before the developer can update the Excel file.

The first thing to do is to update the Suivi Modifications MCDS Aero-Webb Excel file located in:

- GitLab: [Suivi Modifications MCDs Aero-Webb.xls](#)
- WSL: `"/home/username/Workspaces/Aero-Webb/Backend/aero-webb-services/Database/Conception/Suivi Modifications MCDs Aero-Webb.xls"`

Note

Make sure to get the last version updated present in the develop branch.

In this file you need to fill a few columns with information concerning your request.

These information needs to be added in chronological order.

That means after the last request with a date and before the STANDBY in the **Prise and compte et livraison** and the ones with an orange background

Here are the different information:

- The schema receiving the changes.
- The name of the new table or the table receiving changes.
- If it is a new table add a X in the corresponding column.
- The date of the request.
- The type of the target (std or optimal).
- The field or association added/changed.

Info

Use one line per field/association.

- Indicate if the field or association is a primary key with an X in the corresponding column.
- The type of the field in PostgreSQL.
- Indicate if it is an adding, a delete or a modification.
- Do not touch the **Prise en compte et livraison** column.
- The reason of your request and if possible the mantis linked.

First merge request by the developer

Next, the developer pushes an MR that will contain:

- The Excel file updated.

This MR will have a double validation by the TD (Technical direction) and FD (Functional direction). If validated, it will be taken by the TD.

Technical direction actions

Update of the CDM and linked scripts

Once the Excel is modified, the technical direction will take into account the request for the changes in the database.

The TD will update the CDM, generate the database script, create an upgrade script, update the Excel and create a merge request with these modifications.

First merge request by the technical direction

This MR will be taken by the TD and have the following content:

- The cdm and MPD modifications.
- The CREBAS updated.
- The upgrade script : `upgrade_AW_PostgreSQL.sql` .
- The Excel updated with the date.

Java and SQL modifications by the technical direction

When the MR is taken, the TD update the `90_01_update_upgrade_AW7_Postgres.sql` file with the created upgrade script and possibly the complementary script made by the developer.

Then, the TD will update the model classes located in the *domain/model* package, the Helper linked to these classes and will fix the potential compilation problems.

Note

See [History table creation](#) for specific case of the history tables.

Once the model classes are updated, it's time to launch the generators:

- [BIDT](#), if the BIDT model is impacted with the cdm modification.
- [DAO](#)
- [Mapping](#)

Second merge request by the technical direction

This MR will be taken by the TD and have the following content:

- The generated or modified classes.
- The SQL script updated.

Developer actions

Synchronization with develop and new developments

The developer needs to resync with develop in order to get the changes induced by the TD's merge request.

Once the developer is synchronized with develop, he needs to execute the

`90_01_update_upgrade_AW7_Postgres.sql` script on his local database to be in sync with the changes.

Once done, he can start his development.

✓ The packages the developer can change

- The services classes impacted by the changes.
- The DAO which are not generated.
- Etc...

✗ The packages the developer cannot change

- The model classes (domain/model).
- The generated DAO (/gen).
- The mapping classes.

Second merge request by the developer

This MR will be taken by the TD and have the following content:

- The modifications and developments made by the developer in the previous step.
